

Modelling Mining and Oil Projects & Fiscal Regimes

CABRI Dialogue on Extractives

April 2016

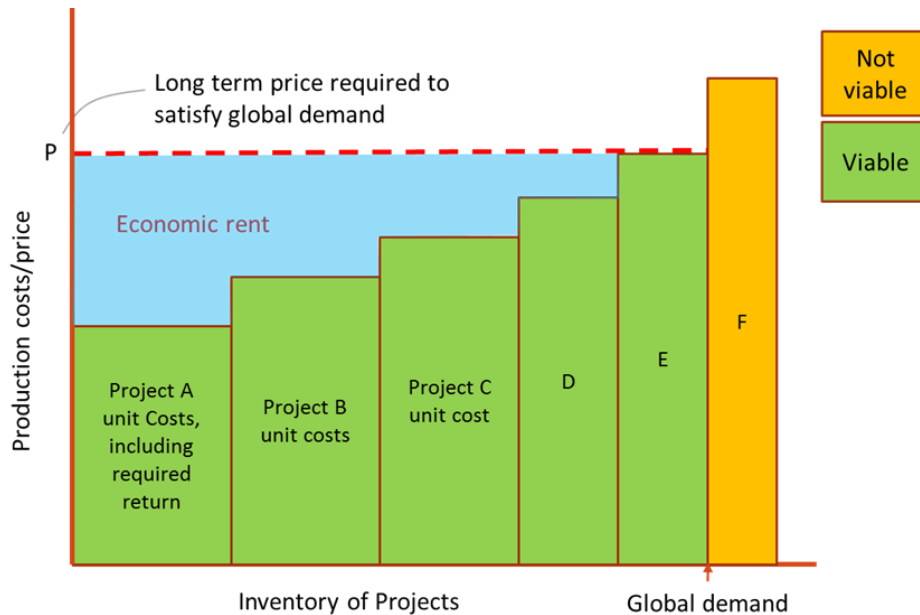

A week's modeling course in 2 hours

1. The background needed to make it all work (rent, life cycle, characteristics)
2. In the market: the impact of cost curves on project revenues
3. The Single Period Model: getting our hands on a model
4. An annualised model: as the investor sees it
5. Some real live models and what they teach us: Tanzania & Mongolia
6. What is needed to embed modeling in public institutions?

Mining, oil & gas Features

- Projects exploit a finite resource
- Long, costly exploration periods
- Significant geological, technical, political, environmental risks
- Large up-front investments
- Sophisticated management and specialized technology
- Prices (mostly) set on international markets; price volatility
- High costs of abandonment
- Significant environmental impact & risks
- High community impact

Economic rent

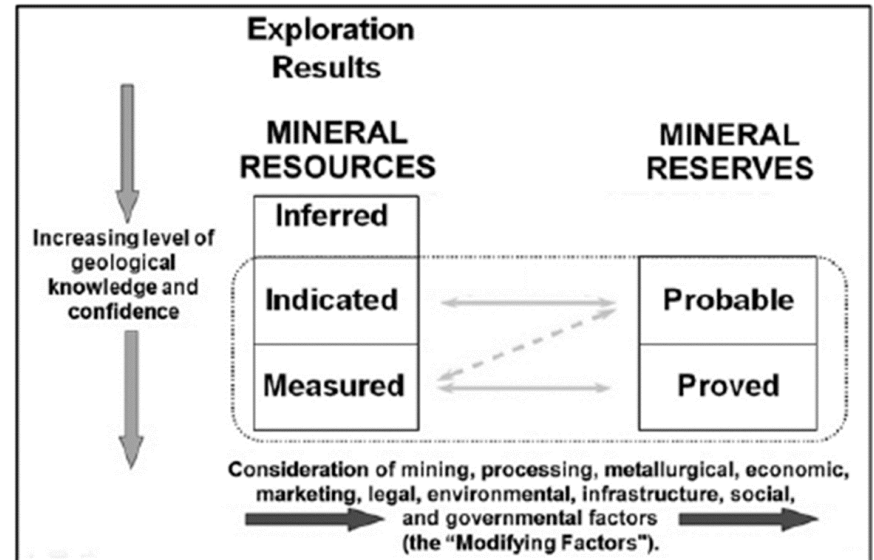

- Deposits vary in size, location & quality. Each therefore has a different production cost
- Investors need to earn at least the production cost plus an acceptable return on investment
- Prices for most commodities are set on international markets. The price needs to be high enough so that the highest-cost project necessary to meet world demand is made just viable
- But that means lower cost projects will make super profits – this is “Economic Rent”: the surplus return above the minimum return necessary to induce the investment
- Economic Rent could (in theory) be captured by the resource owner - not by the extractor – without deterring the investment
- The trouble is, economic rent is (1) Unknown in advance; (2) Uncertain; and (3) Volatile
- Also, to invest in risky exploration investors need to earn enough profit on successful projects to cover failed exploration
- So, “Economic Rent” is a subtle, somewhat subjective concept, but with profound implications for fiscal regime design

Exploration process

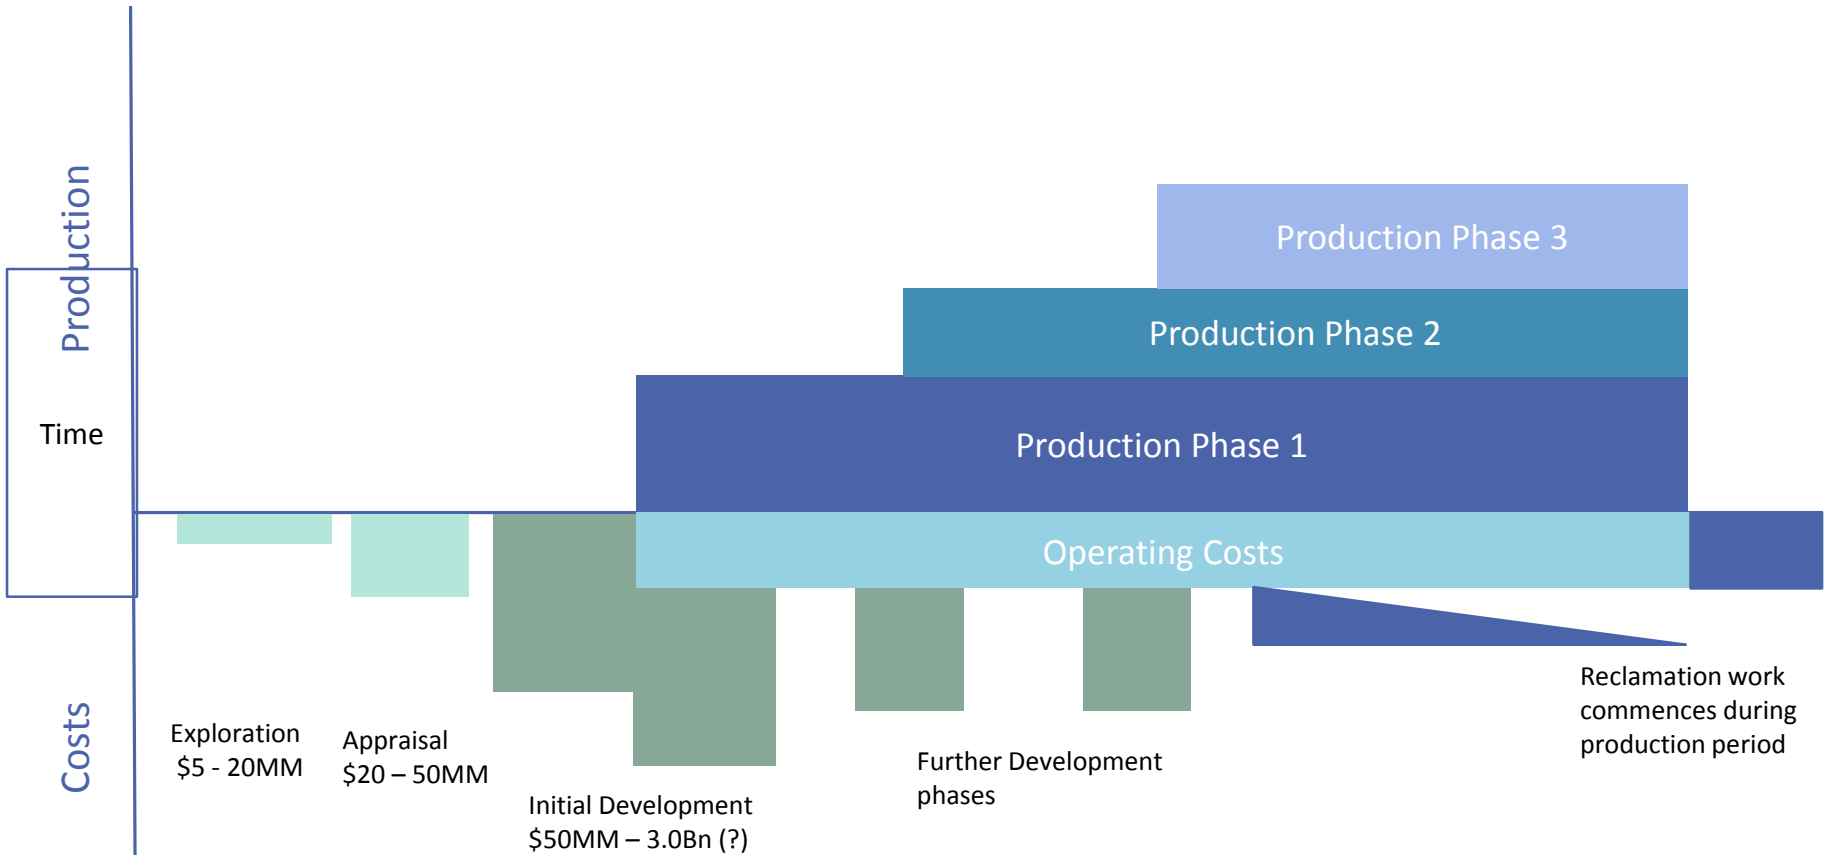

Remote sensing; regional geochemistry; airborne geophysics; seismic surveys

Feasibility study: Mineral Resources
Development plan: Resources reclassified as Mineral Reserves

Mining project life cycle

(basic) Cost categories

Exploration	Searching for deposits
Appraisal	Delineating the size and characteristics of a discovered deposit: Evaluating technical and economic viability
Development costs	Building the project
Operating costs	Producing the mineral: Fixed versus Variable with production
Overheads	Fixed costs of managing production
Sustaining capital	Replacing equipment periodically. Treated as capital cost for tax purposes
Rehabilitation and Decommissioning	Costs of clean up during and after production

"Capital" versus "Operating" costs:

- Capital costs have a benefit beyond a single year, and therefore usually have to be depreciated for tax purposes.
- Operating costs are recurring costs with no lasting benefit, so are expensed immediately for tax

Most economic analysis is done using cashflows where the distinction does not matter, except to calculate tax payments

Capital expenditure often referred to as "Capex". Operating Expenditure as "Opex"

Commodities: supply and demand

What determines the shape of the Supply and Demand curves

Short Term	<ul style="list-style-type: none"> •Prices and demand curves for end-use products •Availability & price of substitutes •Cost to switch 	<ul style="list-style-type: none"> •Flexibility in mine production e.g. putting mines on care and maintenance in price slump •Opec (oil)
Long term	<ul style="list-style-type: none"> •Prices and demand curves for end-use products •Availability & price of substitutes •Cost to switch 	<ul style="list-style-type: none"> •Depletion of existing mines •Geology: unexploited resources and cost to find and extract •Opec Cartel (for oil) •Government policy: e.g. •Access to resources •Fiscal regimes (cost to extract) •Carbon reduction policies •Nuclear power plant usage •Etc.

Inelastic demand

Case study 1: building a cost curve

Imagine a particular mineral which can be produced by only 10 projects in the world.

Source data		
Project	Production	Unit cost
A	100	4.00
B	125	3.00
C	10	9.00
D	50	8.00
E	20	10.00
F	200	2.00
G	50	5.20
H	100	2.75
I	150	2.50
J	45	7.00

Production and Cost curve

Cost curve cast study (questions)

1. If global demand for the mineral is 675 million tonnes, what does the price need to be to ensure production is sufficient?
2. At this price, what profit margins do projects F, make? What profit (as a % of revenue) does project A make?
3. If demand increased to 725 million tonnes, what would that imply for the price?
4. If demand decreased to 575 million tonnes, what would that imply for the price?
5. With demand 675 and price \$4.00, what are the implications of Project I expanding production to 250?

Cost Curve: Solutions

1.If global demand for the mineral is 675 million tonnes, what does the price need to be to ensure production is sufficient?

◦All projects up to and including project A. Price needs to be \$4.00

2.At this price, what profit margins do projects F, make? What profit (as a % of revenue) does project A make?

◦Project F = $(4.00 - 2.00)/4.00 = 50\%$

◦Project H = $(4.00 - 2.75)/4.00 = 31\%$

◦Project A = $(4.00 - 4.00)/4.00 = 0\%$

3.If demand increased to 725 million tonnes, what would that imply for the price?

◦Price increase to \$5.20

4.If demand decreased to 575 million tonnes, what would that imply for the price?

◦Decrease to \$3.00

5.With demand 675 and price \$4.00, what are the implications of Project I expanding production to 250?

◦Price falls to \$3.00. Project A goes out of business...

Mineral valuation: example

	Value of coal in final market	Coal price benchmark
-	Shipping costs	Shipping benchmark
-	Other selling costs (insurance etc.)	Arm's length charges
=	Fair Market Vale FOB Port	Calculated
-	Port handling	Arm's length charges by port
-	Rail costs	Arm's length charges by rail company or actual costs incurred
=	Fair Market Value FOB Mine	Calculated

Project Iron Ore Mine assumptions

Project Assumptions			
Total production	M Tonnes	100	11 years
Sales price: CFR	\$T	100	
Sea freight	\$T	10	
Sales price: FOB port	\$T	90	
<u>Capital costs (Capex)</u>			<u>Operating costs (Opex)</u>
Exploration costs: cash	\$M	50	Operating costs \$T
Exploration costs: sunk	\$M	-	Overheads \$M per year
Development capital	\$M	750	Rail transport \$T
Sustaining capital *	\$M per year	20	
* From yr 2 till 3rd year before production stops			
Decommissioning costs	% DevCapEx	10%	

- Each item here could be broken down further: detailed cost sub-categories etc.
- Choice depends on modelling objective and access to data
- Focus in this course is on fiscal regime modelling: even this aggregated level of detail will give us plenty to analyse

Mining Case Study 1

User to populate the green cells using formulas that pick up source data to derive pre-tax net cashflows for the project over its whole life

Project "X" Single Period Model						
Pre-tax cashflows						\$M
Revenues		MT		\$T FOB port	=	-
Exploration costs						
Development costs						
Sustaining capital		\$M/yr		years		-
Operating costs		\$T		MT	=	-
Overheads		\$M/yr		years	=	-
Rail transport		\$T		MT	=	-
Decommissioning		% DevEx		\$M DevEx	=	-
Total costs						-
Net cashflow before tax						

Data sources in practice

Mining Company: best source
Feasibility studies (EDGAR etc.)
Technical colleagues: Sector ministry
Rules of thumb
Analog projects

Getting good project data out of companies can be challenging...

- Make it a legal requirement
 - Pre-feasibility; Feasibility; Development plan; Annual updates; “Life of Mine” Plans
- Maintain effective working relationship
- Establish agreed formats/templates
- Formally acknowledge that things change: Actual \neq Forecast
 - Companies are hesitant to provide data if they will be held to a previous forecast
- See later discussion on revenue forecasting

Fiscal Tools

Royalty	A share of the value of production 3-5% pretty common, rates often vary by mineral
Income tax	A share of profit, determined under tax rules 30% rate pretty common
Resource Rent Tax	Special tax designed to capture a share of economic rent. Uncommon but often recommended by the IMF
Import duties	% of the value of imports
Value Added Tax	% of sales (output VAT) and % of costs (input VAT) Under properly functioning VAT the consumer should bear the cost – not the mining company. But in practice...
State participation	Government owned company owns a share in the project
Others	Withholding taxes on subcontractors Withholding taxes on dividends and interest

Investment theory: Time = Money

If you have money you can (a) spend it or (b) invest it

You need to be compensated for deferring consumption, which is why interest rates are positive

You have \$1.00 and invest it in a bank for 5 years earning 5% interest

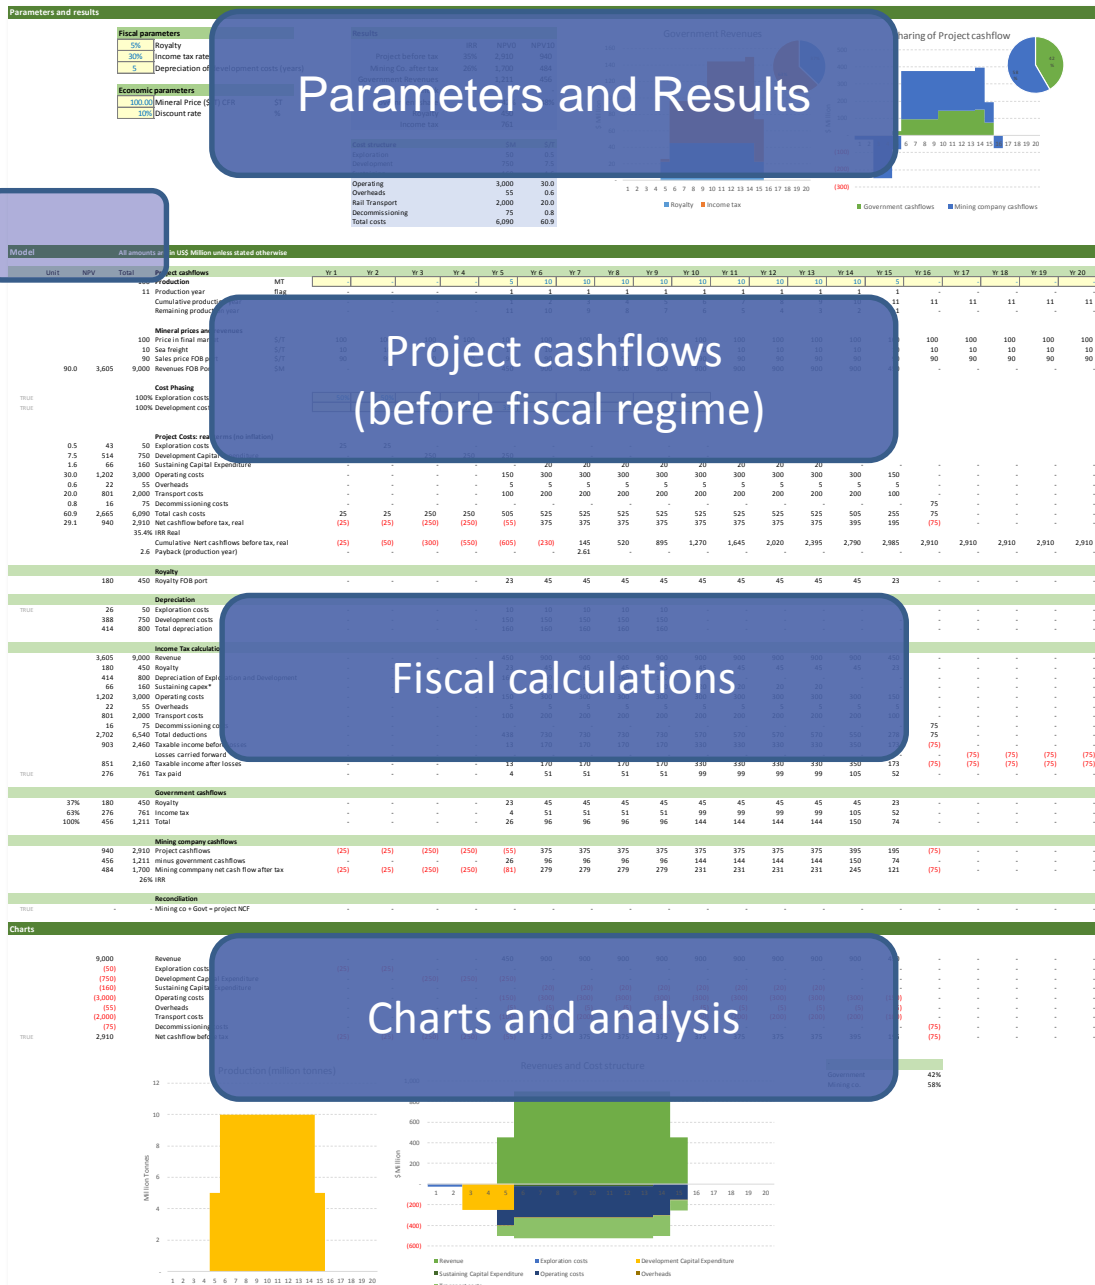

How much is that \$1.00 worth in 5 years? \$1.28

Interest rate		5.00%				
Year		1	2	3	4	5
Opening Balance		0.00	1.05	1.10	1.16	1.22
Investment		1.00				
Interest		0.05	0.05	0.06	0.06	0.06
Closing Balance		1.05	1.10	1.16	1.22	1.28

Generic Mining Fiscal regime

1/ Assuming the RRT is deductible

Columns on left

- Total
- NPV
- Unit \$/tonne
- Checks

Annualized model picks up cost inputs from the single column model. If we update the project inputs on that sheet, the annualized model will automatically update

Walk through annualized model

Deriving pre-tax cashflows

- Building a production profile
- Building the mineral price FOB port each year
- Phasing of exploration and development costs
- Phasing of sustaining capital
- Operating costs
 - Discussion on fixed versus variable, but simplified 100% variable approach in this model
- Phasing of Overheads
- Rail transport costs

- Note that the net cashflow before tax is the same as the single period model

Mining Model: what-ifs

Government

What price would be needed to ensure \$1 billion to the government over the project life time? Or \$1.5 billion?

What royalty rate would be needed to ensure \$1 billion to the government over the project life time? Or \$1.5 billion?

Investor

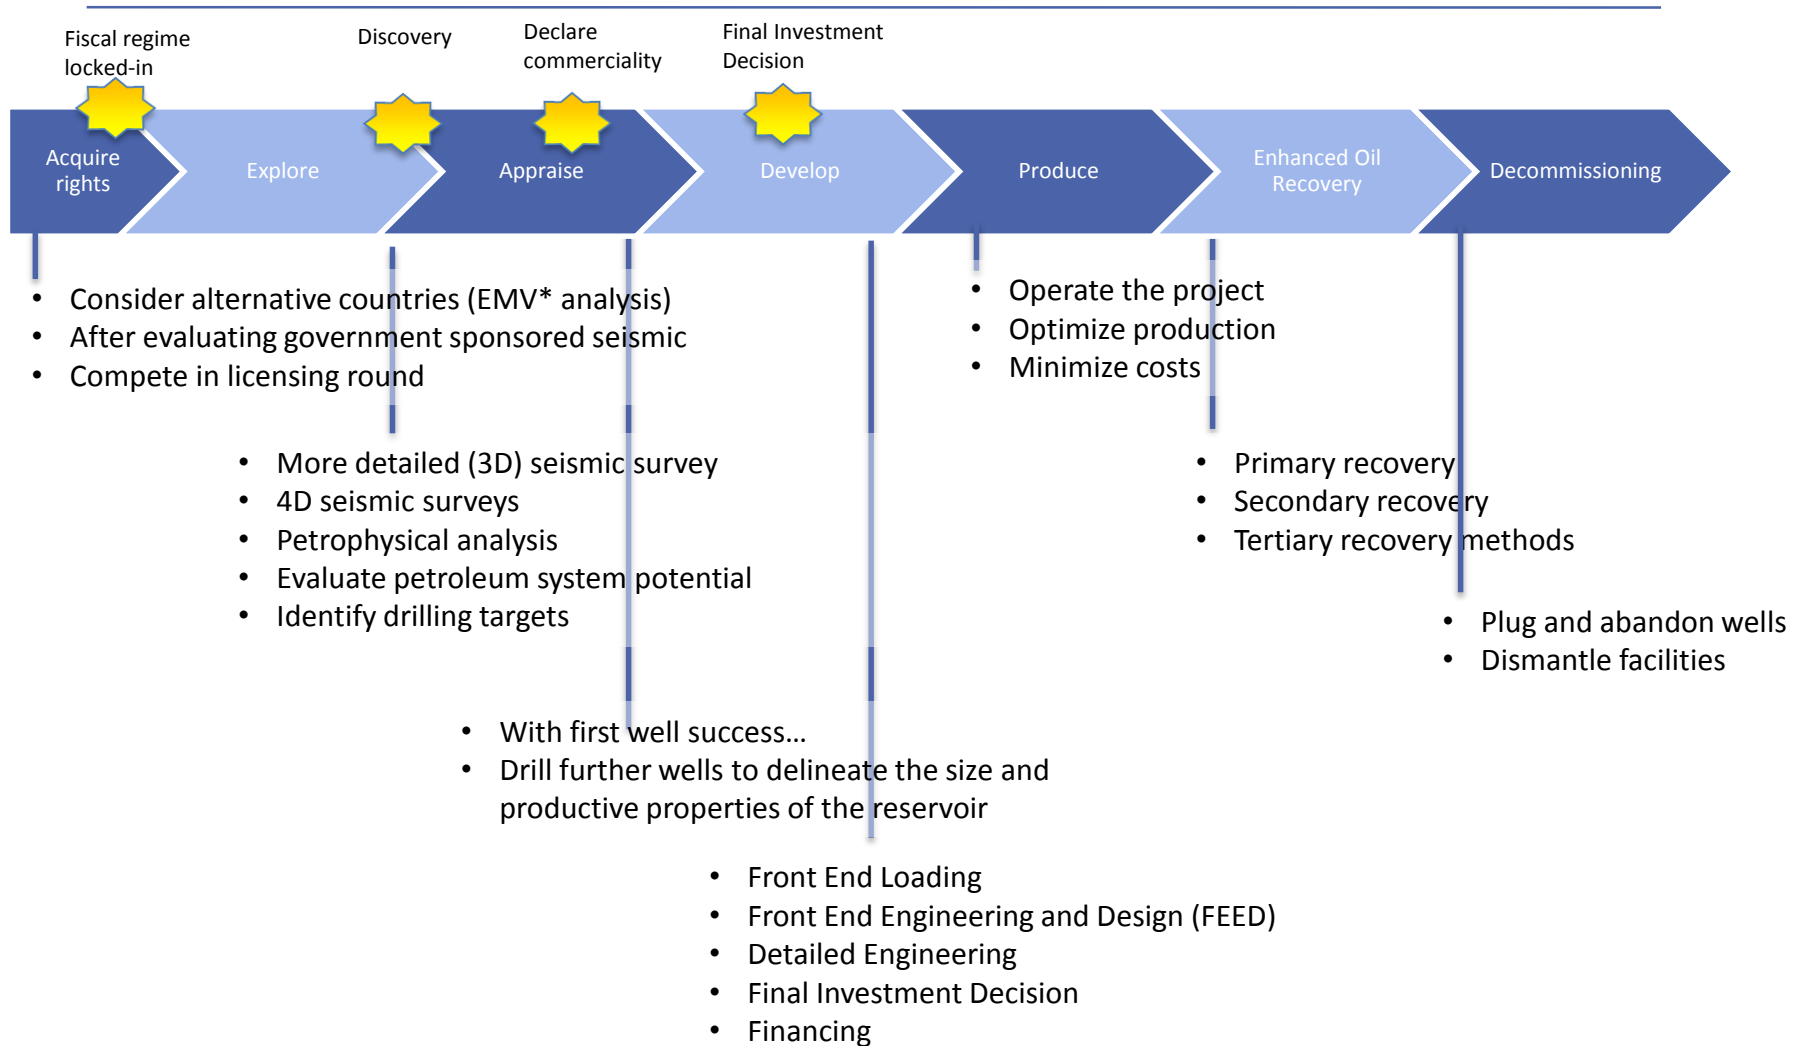

What mineral price would result in 15% project Internal Rate of Return for the investor (IRR)?

What happens to the IRR if we increase the commodity price by 10%?

Interaction Between the Two

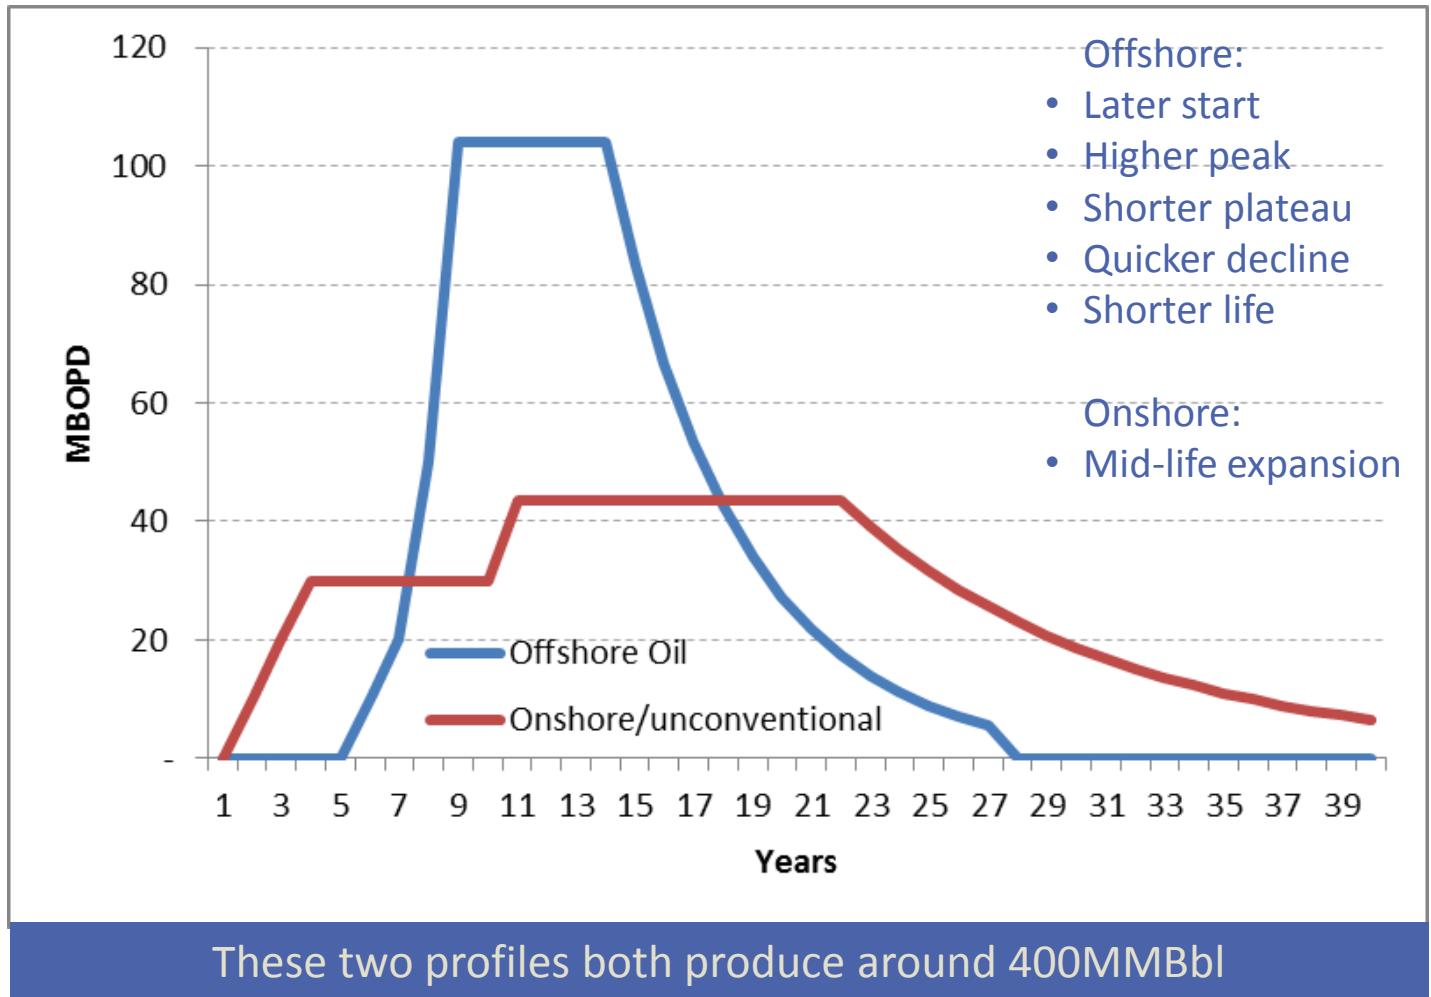

What happens to government revenues if there is a cost overrun of \$500 million?

Petroleum Project Lifecycle

* Expected Monetary value. See later in the course

Onshore vs Offshore Production Profiles

Types of Petroleum Arrangements

**Within enabling legislative framework*

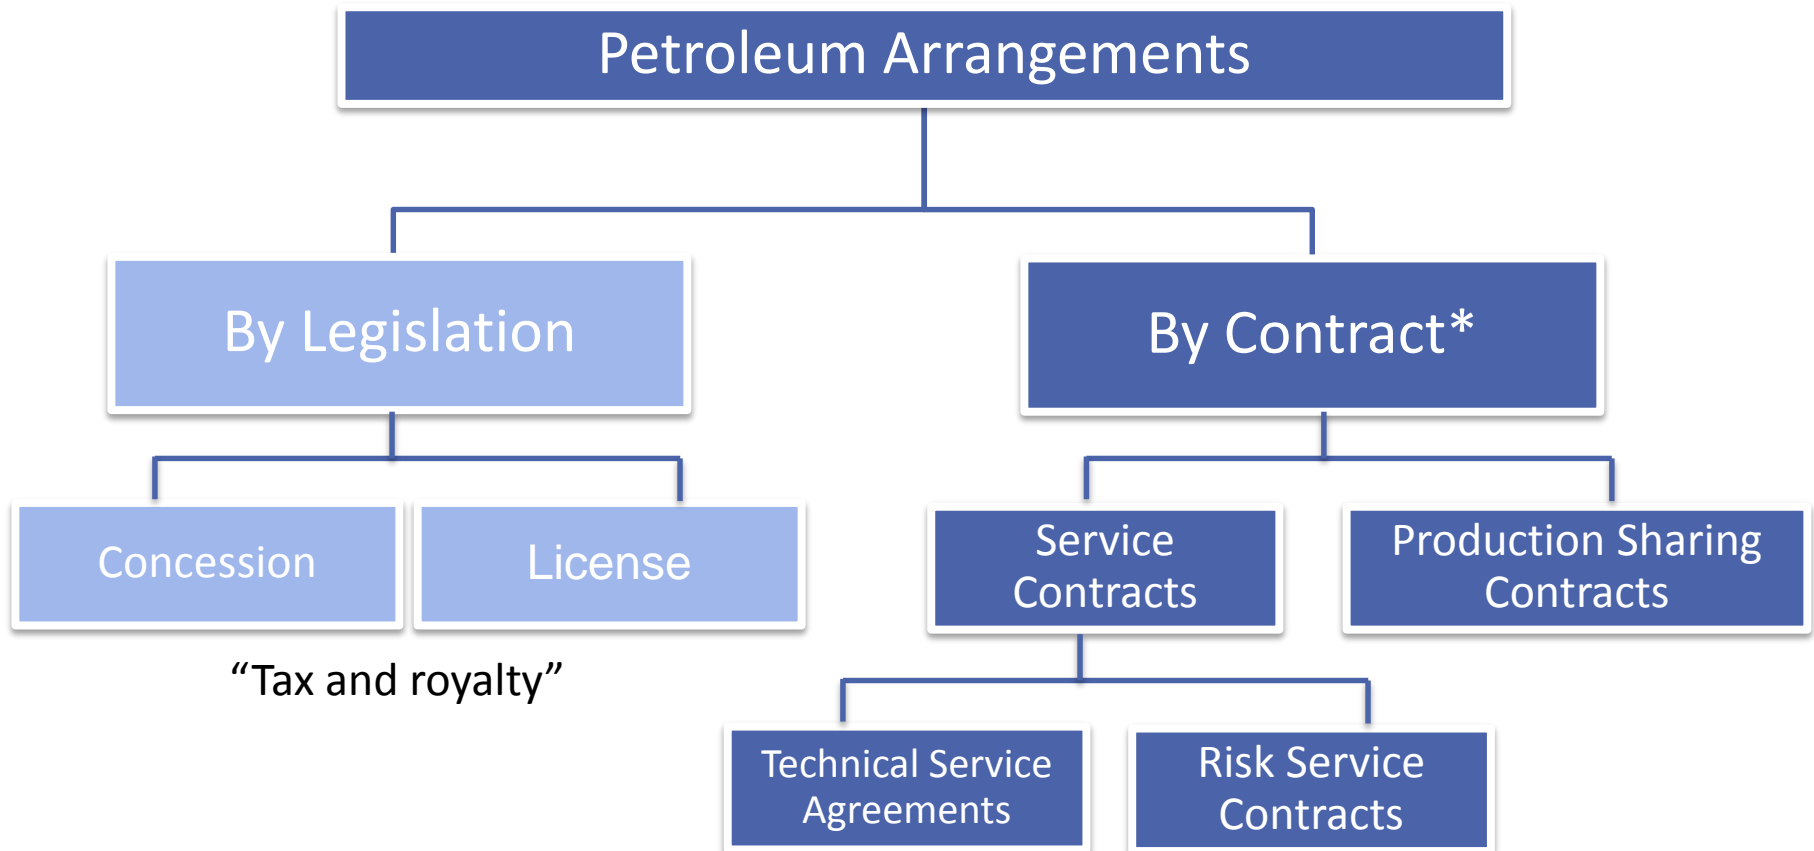

“Tax and Royalty” regime for oil

OilCo licensee
books 100%
minus royalty

Same as mining tax regimes, though because of the potential for higher rent, royalties and tax rates are often higher than mining

Types of Petroleum Arrangements

**Within enabling legislative framework*

Oil Model structure

More complex than mining model:
 Production Sharing
 State Participation

Parameters and results		US\$ Millions	
Parameter	Results	US\$	MM\$
5.025	Priority	0	0
5.026	Production cost	1,000	1,000
5.027	Government share of profit oil	14%	900

Parameters and results

Project cashflows (before fiscal)

Production sharing

State participation

IOC cashflows

IOC tax calculation

Reconciliation

Chart workings

Real 1: Bulyanhulu Gold, Tanzania

Context

Started production in 2001

Over three million ounces of gold

Barrick Gold spun off (2010) to separately listed Acacia Mining

Model: historical production & prices; estimates into the future

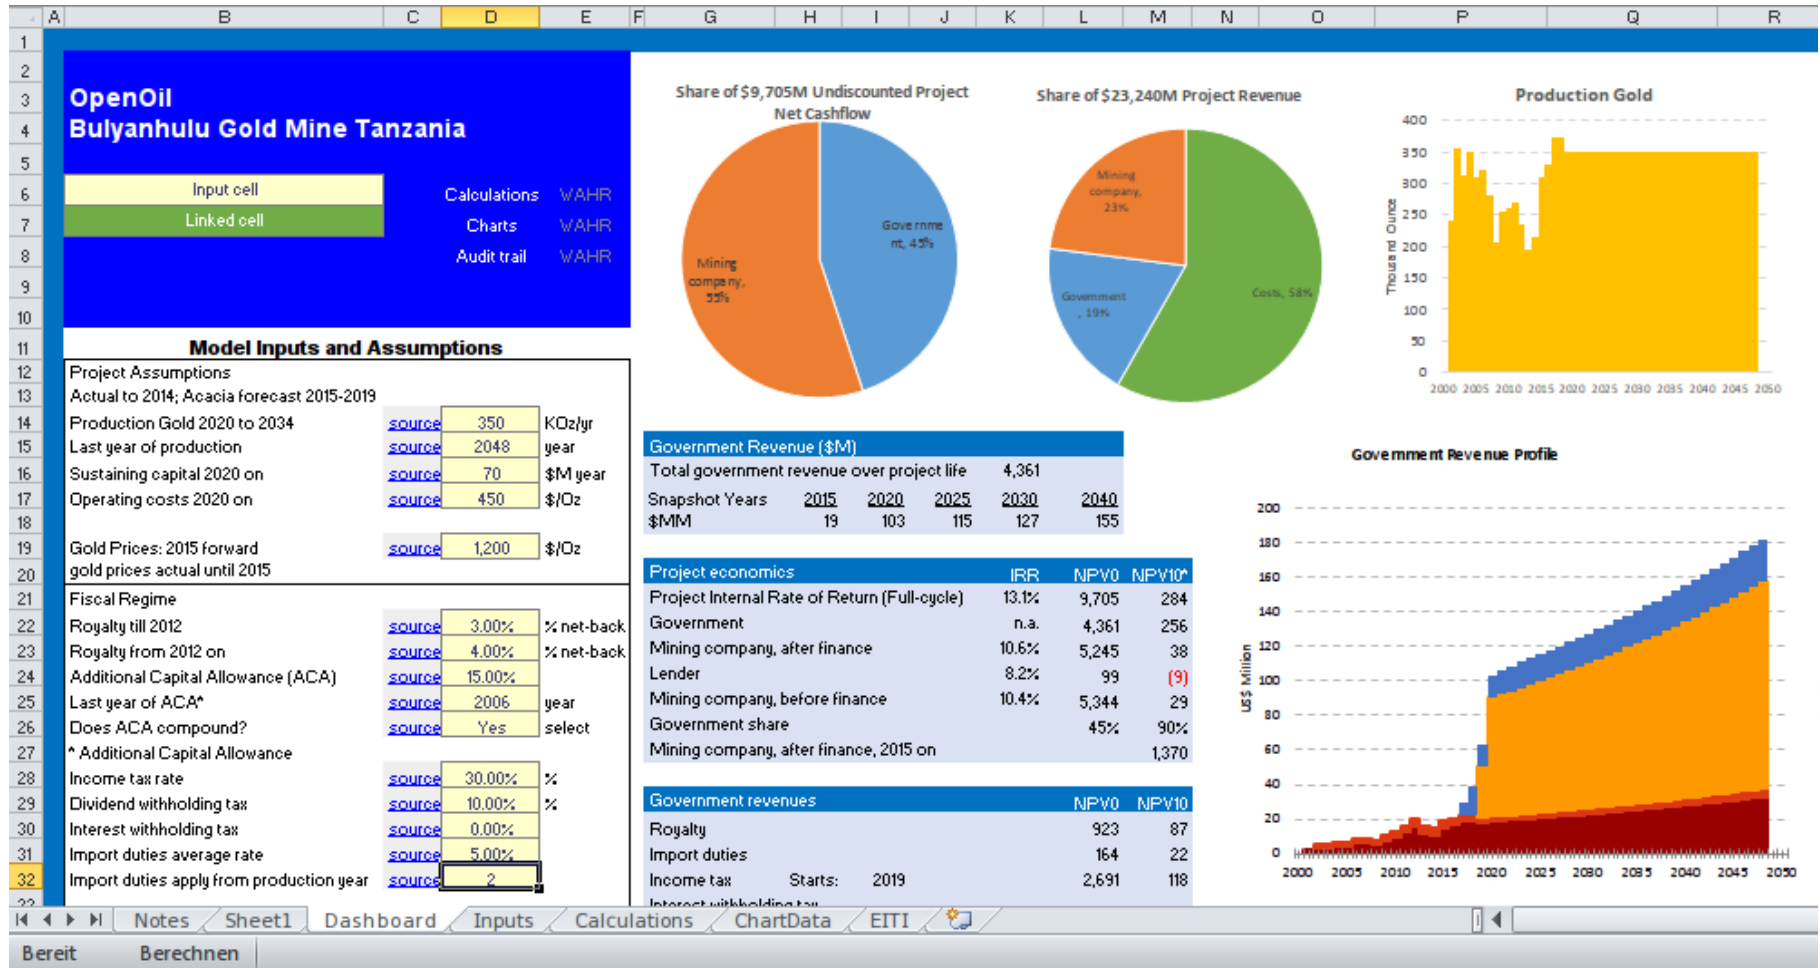

Now: income tax dispute

Still no income tax

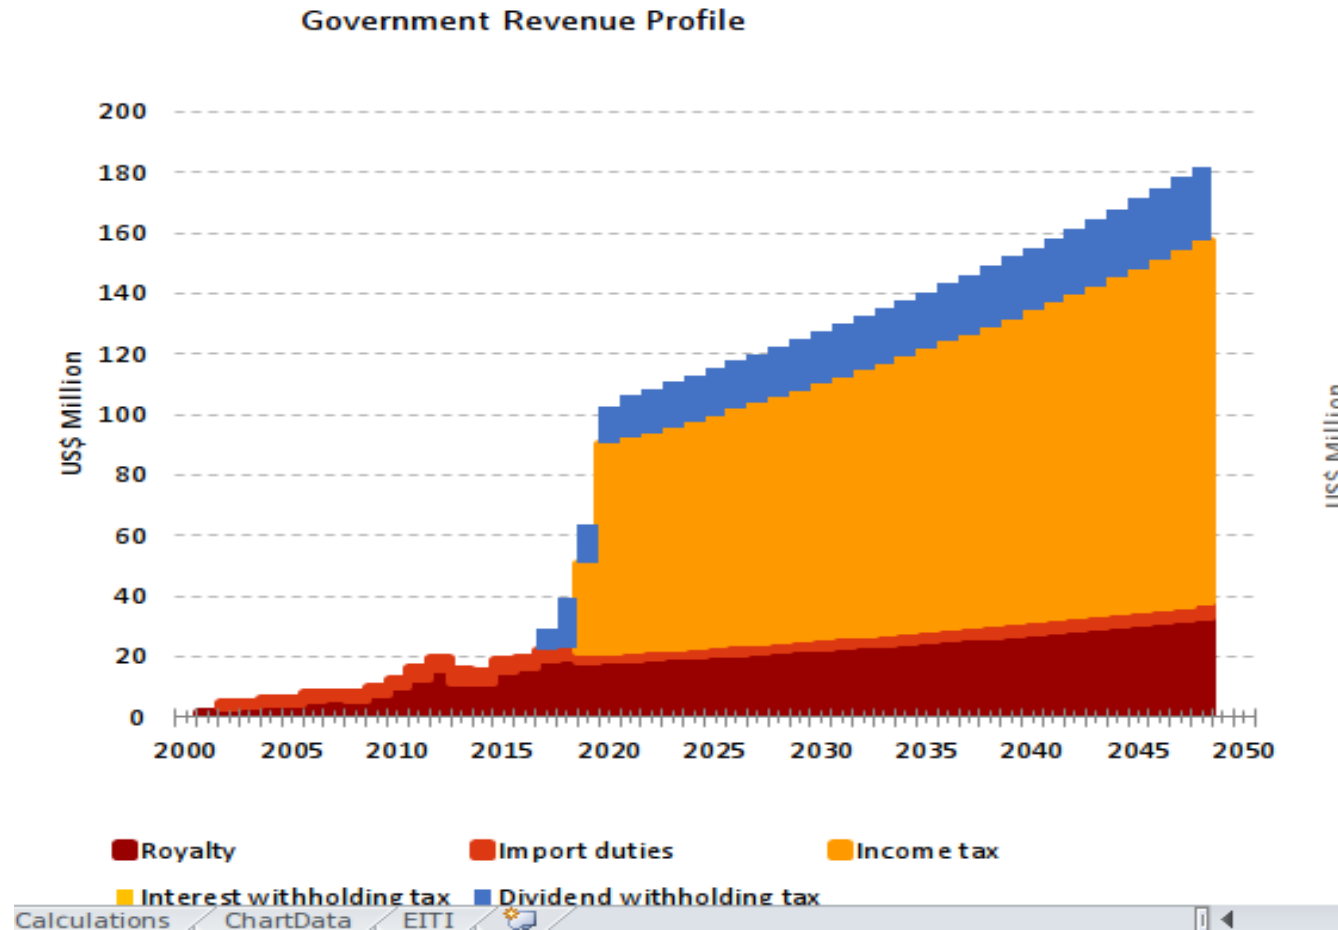

Acacia announced (March): pre-payments of income tax

Tanzanian court: Acacia owes \$42 million dividend withholding tax; company disputes

Buly model overview

Buly model: where is income tax?

Case 2: Oyo Tolgoi, Mongolia

Context

Copper and Gold mine signed in 2002

Taken over by Rio, through an entity called Turquoise Hill

Government negotiated hard fought 34% stake in the venture

Now

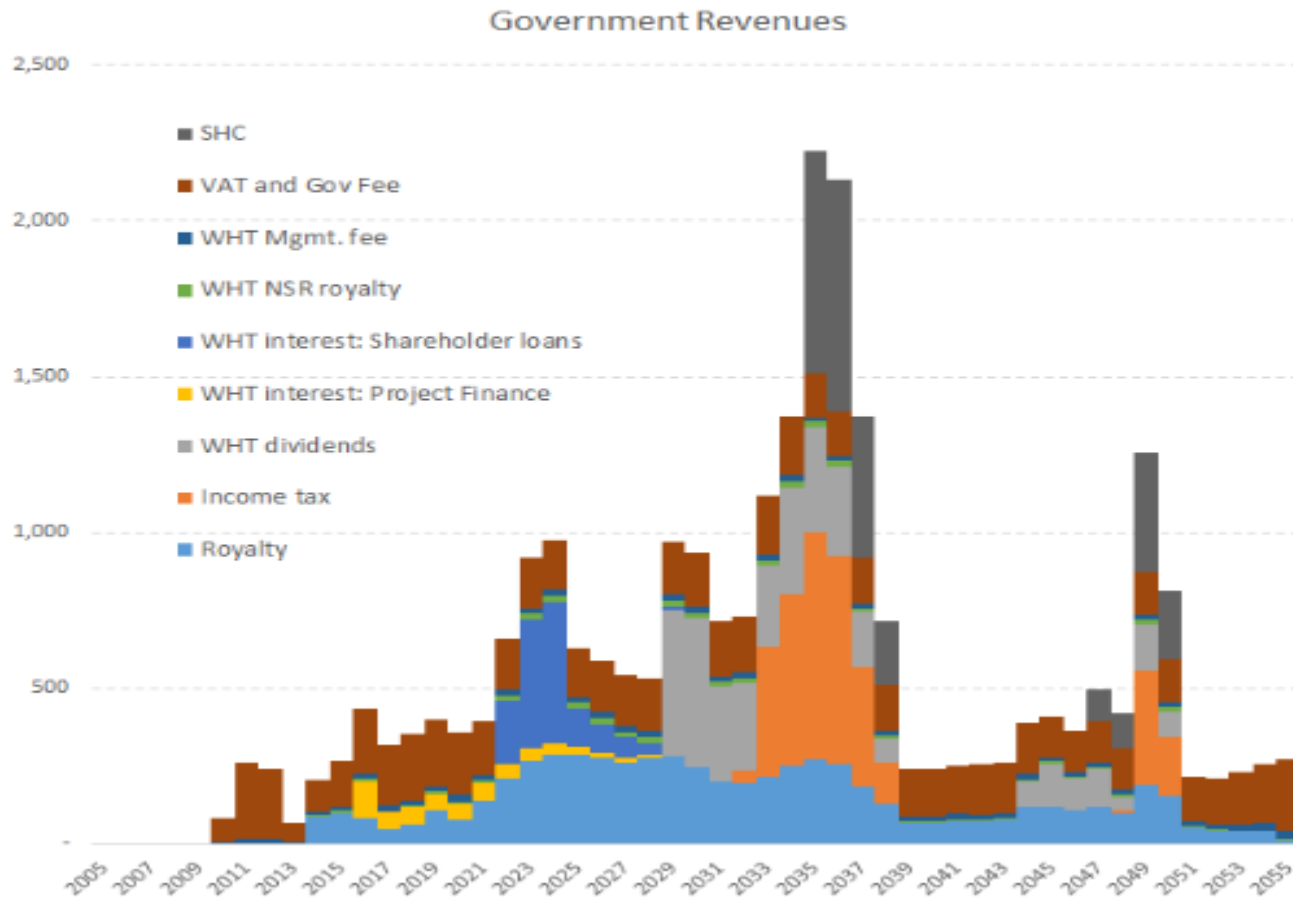

Highly sensitive to prices: 2010-55 NPV is negative in today's prices

Withholding taxes and VAT are significant in early life

The state participation does not earn money until the mid-2030s

Oyo Tolgoi: Waiting for state %

Figure 5: Revenue profile for base case (nominal \$ million)

Has modeling been hard to build?

Challenges:

Complex

Non-standardised

Non-adapted: each model should answer specific questions

Leading to: Slides in presentations, not full workings in model

Ways to meet those challenges:

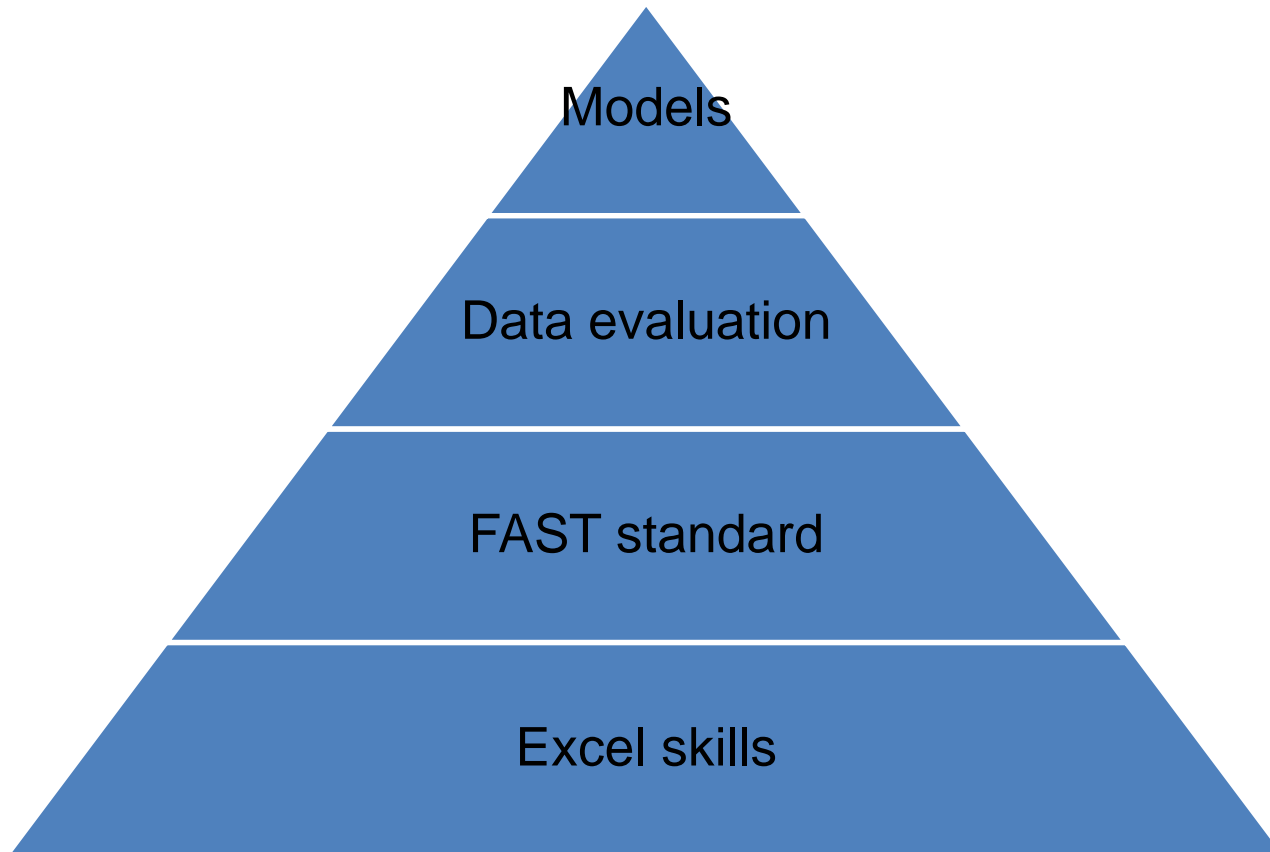

Standardised modeling methodologies across agencies & countries

Full source citation integrated into model

Open modeling processes leading to direct peer review

Leading to: a Public Financial Management paradigm of modeling

Skills pyramid for modeling capacity

the Single Number Super-model
